

R Shiny Tutorial

Hanying Ji

Digital Center – Columbia University Library

What is R Shiny

- An R package that makes it easy to build interactive web apps from R
- Aim: Fully interactive visualization
- JavaScript libraries: d3, Leaflet, and Google Charts.

How R Shiny can be used

- Build dashboard - Tell data story by interacting with data and analysis
- Host any apps on a webpage
- Map interaction

Shiny Gallery:

<https://shiny.rstudio.com/gallery/>

Let's see some example

- Library(shiny)
- runExample("01_hello")

Shiny works in two way:

(1) one script "app.R" which contains:

```
ui <- fluidPage()  
server <- function(input, output){ }  
shinyApp(ui = ui, server = server)
```

(2) two separate scripts "ui.R" and "server.R"

ui.R

```
ui <- fluidPage(  
  titlePanel("Hello Shiny!"),  
  sidebarLayout(          # contains both input and output  
    sidebarPanel(),       # usually contains input  
    mainPanel()           # usually contains output  
  )  
)
```

Let's think:
How all the elements organized?
What are inputs, outputs in this example? How they connect?

Control widgets - Input

http://127.0.0.1:3771 | [Open in Browser](#) |

Basic widgets

Buttons <input type="button" value="Action"/> <input type="button" value="Submit"/>	Single checkbox <input checked="" type="checkbox"/> Choice A	Checkbox group <input checked="" type="checkbox"/> Choice 1 <input type="checkbox"/> Choice 2 <input type="checkbox"/> Choice 3	Date input 2014-01-01
Date range 2017-06-21 to 2017-06-21	File input <input type="file"/> No file selected Browse...	Help text Note: help text isn't a true widget, but it provides an easy way to add text to accompany other widgets.	Numeric input 1
Radio buttons <input checked="" type="radio"/> Choice 1 <input type="radio"/> Choice 2 <input type="radio"/> Choice 3	Select box <select>Choice 1</select>	Sliders 	Text input Enter text...

function	widget
actionButton	Action Button
checkboxGroupInput	A group of check boxes
checkboxInput	A single check box
dateInput	A calendar to aid date selection
dateRangeInput	A pair of calendars for selecting a date range
fileInput	A file upload control wizard
helpText	Help text that can be added to an input form
numericInput	A field to enter numbers
radioButtons	A set of radio buttons
selectInput	A box with choices to select from
sliderInput	A slider bar
submitButton	A submit button
textInput	A field to enter text

Input - SelectInput

```
selectInput( "select_id", h3("This is a label of SelectInput"),  
  choices = list("Choice 1" = 1, "Choice 2" = 2, "Choice 3" = 3),  
  selected = 1  
)
```

Input - SliderInput

```
sliderInput('slider1', h3('This is a label of SliderInput'),  
           min = 0,  
           max = 100,  
           value = c(25,75)  
)
```

Let's do some exercise

- The final ui should look like this

The screenshot shows a Shiny application window with the following components:

- title**: The main title of the application.
- helpText**: A descriptive text block stating "Create demographic maps with information from the 2010 US Census."
- SelectInput**: A dropdown menu labeled "Choose a variable to display" with "Percent White" selected.
- SliderInput**: A slider input for "Range of interest" ranging from 0 to 100, with handles at 0 and 100.
- sidebarPanel**: A sidebar panel containing the helpText, SelectInput, and SliderInput.
- Precent White**, **Precent Black**, **Precent Hispanic**, **Precent Asian**: These are listed as categories or options related to the demographic variable selection.

Control widgets - Output

Output function	Creates
dataTableOutput	DataTable
htmlOutput	raw HTML
imageOutput	image
plotOutput	plot
tableOutput	table
textOutput	text
uiOutput	raw HTML
verbatimTextOutput	text

- Object can be:
 - input from control widgets(Here comes interactive)
 - Directly type in/ insert in

Output - textOutput

```
textOutput("name_give_to_input")
```

Till now, we didn't cover anything about server.R, just think some example of how server.R can be used here.

server.R

```
server <- function(input, output){  
  output$weidget_name <- action  
}
```

The server can use

- (1) the input from ui,
- (2) the result of the action(output\$weidget_name) can be used in ui by calling the object's name.

That's the reason why it is a function which takes two parameters.

Let's do some exercise

Paste the input value of the selectInput with “You select ”, then show it in the mainpanel

Hint: The action here called “renderText”

Use Reactive expressions

Reactive expressions let you control which parts of your app update when, which prevents unnecessary computation that can slow down your app.

- A reactive expression saves its result the first time you run it.
- The next time the reactive expression is called, it checks if the saved value has become out of date (i.e., whether the widgets it depends on have changed).
- If the value is out of date, the reactive object will recalculate it (and then save the new result).
- If the value is up-to-date, the reactive expression will return the saved value without doing any computation.

Let's see an example

```
fib <- function(n) ifelse(n<3, 1, fib(n-1)+fib(n-2))

server <- function(input, output) {
  currentFib <- reactive({ fib(as.numeric(input$n)) })
  output$nthValue <- renderText({ currentFib() })
  output$nthValueInv <- renderText({ 1 / currentFib() })
}
```

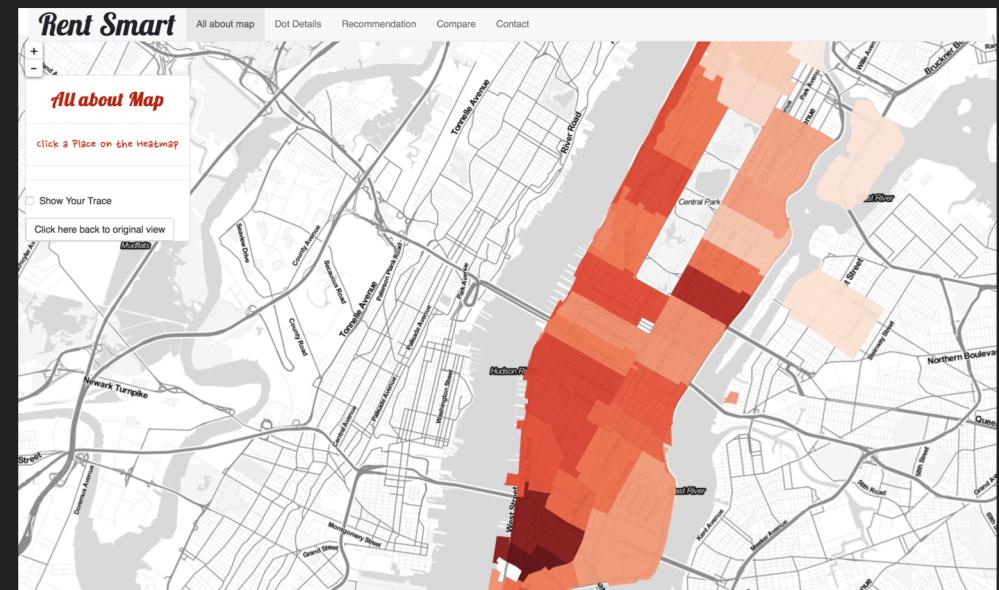

We want the `textOutput` reactive with the input `n` but don't slow down our app.

If we don't use reactive object `currentFib()`, every time we make any change in our app and execute the second line in `server` function, it will go back to check the `input$n` no matter it change or not.

`reactive` can store the value unless it is updated

Topic - Leaflet

- Leaflet is one of the most popular open-source JavaScript libraries for interactive maps. It's used by websites ranging from The New York Times and The Washington Post to GitHub and Flickr, as well as GIS specialists like OpenStreetMap, Mapbox, and CartoDB.

<https://github.com/TZstatsADS/Spring2018-Project2-Group3>

Basic Usage

Do you still remember how **ggplot2** works?

- Create a map widget by calling `leaflet()`.
- Add *layers* (i.e., features) to the map by using layer functions (e.g. `addTiles`, `addMarkers`, `addPolygons`) to modify the map widget.
- Repeat step 2 as desired.
- Print the map widget to display it.

```
leaflet() %>%  
  addTiles() %>% # Add default OpenStreetMap map tiles  
  addMarkers(lng=174.768, lat=-36.852, popup="The birthplace of R")
```
